# Chapter 1

## Introduction

1.1 Motivation

1.2 Aims and Objectives

1.3 Overview

## Chapter 2

# Background

”By definition, a complex number  $z$  is an ordered pair  $(x, y)$  of real numbers  $x$  and  $y$ , written  $z = (x, y)$ ” [Kreyszig, 2010]. In practice, complex numbers are written in the form  $z = x + iy$ , where  $x$  and  $y$  are real numbers and  $i$  is the imaginary unit. The set of complex numbers is denoted by  $\mathbb{C}$ .

### 2.1 The $\mathcal{Z}$ -Transform

Come up with a more catchy Z-Transform title

The  $z$ -transform is a transformation of a real or complex continuous time function  $x(t)$ , often used for discrete time signals and is commonly described as the discrete time Fourier transform (DTFT). Taking the Fourier transform of a sampled function results in

$$\mathcal{F}\left[x(t) \sum_{n=-\infty}^{\infty} \delta(t - n\Delta t)\right] = \int_{-\infty}^{\infty} x(t) \sum_{n=-\infty}^{\infty} \delta(t - n\Delta t) e^{-j\omega t} dt \quad (2.1)$$

We can then make use of the sifting property of the delta function.

$$= \sum_{n=-\infty}^{\infty} \int_{-\infty}^{\infty} x(t) \delta(t - n\Delta t) e^{-j\omega t} dt \quad (2.2)$$

$$= \sum_{n=-\infty}^{\infty} x(n\Delta t) e^{-j\omega n\Delta t} \quad (2.3)$$

If we normalise the sampling interval to 1, we get

$$\sum_{n=-\infty}^{\infty} x(n) e^{-jn\omega} \quad (2.4)$$

The sequence  $x(n)$  is sampled at discrete time intervals  $t_n = n\Delta t$ , where the sampling interval  $\Delta t$  is the time between consecutive samples and the time index  $n$  numbers the samples. The DTFT is a periodic function of  $\omega$  with period  $2\pi$ . The existence of the DTFT relies on the condition of absolute summability of the sequence  $x(n)$ ; all the terms must converge to a finite value. This requirement is mathematically expressed as

$$\sum_{n=-\infty}^{\infty} |x(n)| < \infty \quad (2.5)$$

We can extend our analysis to the  $Z$ -transform, which generalizes the discrete time Fourier transform to the complex plane, not just the unit circle where  $r = 1$ . The  $Z$ -transform of a sequence  $x(n)$  is formally given by

$$X(z) = \mathcal{Z}_{n \rightarrow z}[x(n)] = \sum_{n=-\infty}^{\infty} x(n)z^{-n} \quad (2.6)$$

For a complete description of  $z$  in the complex plane, we tend to its polar form  $z = re^{i\theta}$ , where  $r$  represents the magnitude of  $z$  and  $\theta$  (often written as  $\omega$  in the context of the unit circle for the DTFT) represents the angle of  $z$  with respect to the positive real axis.

In the analysis of causal systems - systems for which a time origin is defined and is illogical to consider signal values for negative time - the unilateral  $Z$ -transform is used. Unlike the bilateral  $Z$ -transform in (2.6), summing from zero to positive infinity yields the unilateral  $Z$ -transform defined to be

$$X(z) = \mathcal{Z}_{n \rightarrow z}[x(n)] = \sum_{n=0}^{\infty} x(n)z^{-n} \quad (2.7)$$

The region within the complex  $z$ -plane where (2.7) converges is known as the Region of Convergence (ROC). If we say that  $z_1$  converges, then  $z_1$  exists within the ROC. Thus, all  $z$  such that  $|z| > |z_1|$  also converge. Strictly speaking, the ROC is defined for the set of values of  $z$  for which the  $Z$ -transform is absolutely summable

$$\mathbf{ROC} = \left\{ z : \sum_{n=0}^{\infty} |x(n)z^{-n}| < \infty \right\} \quad (2.8)$$

The ROC for causal sequences is typically the exterior of the outermost pole in the  $Z$ -plane, denoted as  $|z| > a$ . This region excludes the poles themselves, as the transform does not converge at those points. For the system to be *stable*, it's essential that the ROC includes the unit circle,  $|z| = 1$ . Thus, all poles must lie within the unit circle [Loveless and Germano, 2021].

### 2.1.1 Probability Generating Functions

May be better to move within Abate and Whitt's method

## **2.2 The Inverse $\mathcal{Z}$ -Transform**

### **2.2.1 Abate and Whitt 1992**

### **2.2.2 Cavers 1978**

### **2.2.3 Series acceleration techniques**

## **2.3 Discrete Pricing Options**

# Chapter 1

## Aims and Objectives

### 1.1 Aims

We aim to understand a new efficient method for numerical evaluation of the inverse Z-transform, which states to be faster and more accurate than the standard trapezoid rule. A specific area of applying this method would be to the pricing of discretely monitored exotic options, such as lookback and barrier options, and see how it compares to other methods; Abate and Whitt's approach, C. Cavers' method with Euler, Shanks and epsilon accelerations, etc.

### 1.2 Objectives

- Understanding Levendorskii's inverse Z-transform and the common numerical evaluation methods
- Implementing the function as a code
- Numerical benchmarking; average error, maximum error and CPU time
- Exploring its uses in discrete pricing options

### 1.3 Deliverables

- numerical benchmarking results to add to '*Review of numerical inversion techniques of the z-transform*' by Loveless and Germano
- results and implementation in regards to discrete pricing options (*Accurate numerical inverse z-transform and its use in the Fourier-z pricing of discretely monitored path-dependent options* by Loveless, Phelan and Germano)

# Chapter 2

## Work Plan

### 2.1 Project Start $\rightarrow$ 30<sup>th</sup> November '23

- background reading on complex numbers & contour integration based methods, fourier transform,  $z$ -transform and its inverse, numerical approaches to inverse  $z$ -transform and pricing options (barrier and lookback options)
- coding implementation of Levendorskii's inverse  $z$ -transform

### 2.2 1<sup>st</sup> December '23 $\rightarrow$ 24<sup>th</sup> January '24

- preliminary research on Loveless' and Germano's '*Review of numerical inversion techniques of the  $z$ -transform*'
- understanding the other methods; AW, C, CEuler, CShanks and CEpsilon
- going over the different functions; Heaviside Step, Polynomial, Decaying Exp, Sinusoidal
- reviewing the code for numerical benchmarking
- implementing it for Levendorskii's method
- begin work on interim report

### 2.3 24<sup>th</sup> January '24 $\rightarrow$ 15<sup>th</sup> March '24

- preliminary recap on discrete pricing options (barrier and lookback options) and the need for  $z$ -transform
- use-case in discrete pricing options
- start work on project report; however, to be worked on throughout the year/stages

### 2.4 5<sup>th</sup> March '24 $\rightarrow$ 26<sup>th</sup> April '24

- extra time to deal with any unexpected problems or delays
- final touches
